TITLE

[1] ENDOTHELIAL SPECIFIC TARGETING

X.

This non-provisional application claims the benefit under 35 U.S.C. 119(e) of U.S. provisional application 60/189,793 filed March 16, 2000.

FIELD OF THE INVENTION

The present invention relates generally to small peptide motifs which critically determine molecular specificity and possibly function relating to molecular targets of the tumor endothelium.

BACKGROUND OF THE INVENTION

[4]

Vascular endothelial cells cover the entire inner surface of blood vessels in the body. They play an important role in tissue homeostasis, fibrinolysis and coagulation, blood-tissue exchange, vascularization and neoplastic tissues, and blood cell of normal during physiological migration activation and pathological processes. A unique aspect of endothelial that although they present many is functional and morphological features, they also display remarkable heterogeneity in different organs. been shown that bovine aortic endothelial cells, when co-cultured with cells or matrix proteins from various organs, will change their phenotype to reflect their interaction with that particular tissue type. phenotypes are, in part, mediated by molecular markers, which are expressed by these endothelial cells specific for the unique interaction. Based on the unique histologic appearance of tumor vasculature,

[5]

postulated that expression of specific molecular endothelial markers probably also exist for the tumor-endothelial interaction. The ability to target these molecules would, in effect, specifically target the tumor endothelium, and hence, the tumor. Previous attempts to identify and target these specific molecular endothelial molecules have failed.

Ŧ

The importance of pathologic angiogenesis is well established in the clinical setting of cancer. Solid tumors are unable to grow much larger than 2 mm in diameter without a blood supply, and in order to express a malignant phenotype, tumors must induce new vessel Tumors recruit endothelial cells during the growth. The recruited endothelial process of angiogenesis. cells differentiate and express unique molecular markers specific for their association with tumor cells. ability to identify and target these molecular markers of the allow for specific targeting Currently, vasculature as well as the tumor itself. there are no viable directed therapies targeting the endothelial cells and therapies are needed to provide novel and specific treatment alternatives.

identification of tissuerecently, [6] Until specific endothelial markers has progressed slowly, partly because of difficulties in isolating populations of endothelial cells from tissues. powerful technique utilizing phage display peptide been developed that allows for libraries has selection of peptide sequences with desired binding specificities. In this system, peptides with as many as 109 permutations are expressed on the phage surface by fusion with a phage surface protein. The desired peptides are selected on the basis of binding to the target molecule. The strength of this technology is its ability to identify interactive proteins and other molecules without pre-existing notions about the nature of the interaction.

[7]

Using this methodology, various peptides with binding specificity to angiogenic endothelium various have endothelial cells from organs These peptide sequences are typically three identified. amino acids in length and the best characterized of these sequences is represented by the RGD (Arg-Gly-Asp) This sequence was originally discovered in motif. fibronectin, and later re-identified using in vivo phage peptide display library animal experiments. RGD is the cell attachment site for many other adhesive proteins.

[8]

The finding that only 3 amino acids would form an essential recognition site for cells in a very initially received with large protein was skepticism. However, the observation was soon confirmed with regard to fibronectin and then extended to other Since then, other peptide motifs that proteins. identify and bind to specific targets on the endothelial cells of angiogenic vessels, brain, lungs, retina, and have been reported (Table 1). Also, the kidneys functional specificity of the 3-amino acid motif, NGR for (Arg-Gly-Asp), has recently been described It is important to point out angiogenic endothelium. reported motifs with binding to the specific for endothelium are, in fact, angiogenic endothelial cells and not specific for tumor-derived endothelium.

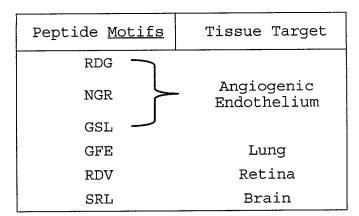

Table 1. Reported Peptide Motifs and Targeted Tissue

SUMMARY OF THE INVENTION

[9]

Embodiments of the present invention include purified peptide fragments with selective binding to tumor-derived endothelial cell, wherein the peptide fragment possesses a charge motif of positive-positive-neutral hydrophobic (++0). In a preferred embodiment, these purified peptide fragments have an amino acid length of between 2 and 50 residues.

[10]

embodiment of the invention Α further includes the purified peptide fragments described above wherein the peptide fragment is operatively attached to a therapeutic agent capable of exerting a cytotoxic effect on tumor vasculature. Furthermore, this peptide fragment operatively attached to a therapeutic agent may exert a cytotoxic effect on tumor vasculature sufficient to lead to tumor necrosis. Additionally, these peptide formulated as а pharmaceutical fragments may be composition.

[11]

In further embodiments, purified peptide fragments of the present invention are linked to a diagnostic agent that is detectable upon imaging, such

[12]

diagnostic agents include: paramagnetic, radioactive or fluorogenic ion. Specifically, the diagnostic agents utilized in embodiments of the invention include: chromium (III), manganese (II), iron (III), iron (III), cobalt (II), nickel (II), copper (II), neodymium (III), samarium (III), ytterbium (III), gadolinium (III), vanadium (II), terbium (III), dysprosium (III), holmium (III), erbium (III), iodine¹²³, technetium^{99m}, indium¹¹¹, rhenium¹⁸⁸, rhenium¹⁸⁶, copper⁶⁷, iodine¹³¹, yttrium⁹⁰, iodine¹²⁵, astatine²¹¹, and gallium⁶⁷.

of embodiments the present Additional invention include compositions useful for targeting tumor-derived endothelial cells, the composition being group peptide selected from the comprised of a consisting of SEQ ID NO:1 (Cys-Gly-Gly-Arg-His-Ser-Gly-Gly-Cys), SEQ ID NO: 2 (Cys-Gly-Gly-Arg-Lys-Leu-Gly-Gly-Cys), SEQ ID NO:3 (Cys-Gly-Gly-Arg-Arg-Leu-Gly-Gly-Cys), SEQ ID NO: 4(Cys-Gly-Gly-Arg-Arg-Ser-Arg-Gly-Gly-Cys) and SEQ ID NO:5(Cys-Leu-Leu-Arg-Arg-Ser-Arg-Leu-In additional embodiments of the present Leu-Cys). invention, the compositions described above may include a peptide capable of being operatively attached or operatively attached to a therapeutic agent that is capable of exerting a cytotoxic effect vasculature, which in some instances may be sufficient to lead to tumor necrosis. Additionally, in additional embodiments of the invention these compositions may be formulated as a pharmaceutical composition.

In a further embodiment, the composition of the present invention described above is attached to a therapeutic agent which includes at least one of the following anticellular agents: a steroid, an

[14]

antimetabolite, an anthracycline, a vinca alkaloid, an antibiotic, an alkylating agent, an epipodophyllotoxin, a plant-, fungus- or bacteria-derived toxin. Similarly, embodiments of the invention include composition of the present invention described above is attached to a therapeutic agent which includes at least one of the following cytotoxic agents: an A chain toxin, a ribosome .alpha.-sarcin, gelonin, protein, inactivating restrictocin, a ribonuclease, diphthia aspergillin, toxin, Pseudomonas exotoxin, a bacterial endotoxin, or the lipid A moiety of a bacterial endotoxin.

In additional embodiments, compositions of the present invention include peptides which are linked to a diagnostic agent that is detectable upon imaging, include: paramagnetic, diagnostic agents such Specifically, the radioactive or fluorogenic ion. diagnostic agents utilized in embodiments the invention include: chromium (III), manganese (II), iron (III), iron (II), cobalt (II), nickel (II), copper (II), samarium (III), ytterbium (III), (III), neodymium (II), terbium gadolinium (III), vanadium dysprosium (III), holmium (III), erbium (III), iodine 123, technetium^{99m}, indium¹¹¹, rhenium¹⁸⁸, rhenium¹⁸⁶, copper⁶⁷, $iodine^{131}$, $yttrium^{90}$, $iodine^{125}$, $astatine^{211}$, and $gallium^{67}$.

Includes a method for treating a diseased state in a mammal wherein the following is administered: an effective amount of a peptide fragment with selective binding to tumor-derived endothelial cells, wherein the peptide fragment possess the charge motif of positive-positive-neutral hydrophobic (++0). The diseased state may include chronic inflammatory diseases.

- [16] Embodiments of the present invention include peptide motifs/targeting peptides that define specificity of tumor-derived endothelial cells.
- [17] Embodiments of the present invention will facilitate anti-angiogenic therapies to be used either alone or in conjunction with standard anti-angiogenic therapies.
- [18] Furthermore, embodiments of the present invention include methods for use in diagnostic imaging tools for the detection of very small metastasis, as well as for monitoring tumor response to treatments.
- [19] An additional embodiment of the present invention encompasses targeting and directing chemotherapy drugs to the tumor.
- [20] Still further embodiments of the invention include treatments for chronic inflammatory diseases such as rheumatoid arthritis and psoriasis, as well as for some forms of blindness.
- [21] The present invention and its preferred embodiments will be better understood by way of reference to the detailed disclosure and to the accompanying drawings described hereinbelow.

DETAILED DESCRIPTION OF THE PRESENT INVENTION

The present invention includes a system that can be used to identify specific molecular targets of the tumor endothelium. Given that small peptide motifs are able to critically determine molecular specificity and therefore function, a need was recognized in connection with identifying small peptide sequences or fragments, preferably less than 50 amino acids in length, that could define specificity of TDEC. An additional need included the determination of whether the physical characteristics of charge conformation of these motifs is important for the specificity.

[31]

The following rationale formed the basis of the identification of the molecular motifs in accordance with at least one embodiment of the present invention. endothelial non-transformed cells are Importantly, The genetic information of cancer cells is cells. inherently unstable, and tumor cells can mutate and previously responsive develop resistance to a therapeutic modality much faster than a genetically stable population of cells, such as "normal" (i.e., non-Peptide molecules that cancerous) endothelial cells. are able to bind to tumor endothelium specifically could be useful as a delivery vehicle for directing cytotoxic Selectively increasing agents to the tumor. concentration of a cytotoxic agent within the tumor would affect not only the endothelial cells but also the Mortality due to cancer is the result of tumor cells. uninhibited and metastatic growth of the cancer made Therefore, possible by the tumor vasculature. ability to destroy tumor vasculature leading to the would metastasis growth and cancer deterred disease of this outcome significantly impact the Thus, the present invention will facilitate specific this directed treatment as an endothelial marker that is effective across many vertebrate species.

[32]

A number of systems have been developed in recent years that allow for the selection of sequences with desired binding specificities from highly diverse, randomly generated peptide libraries. (For example, see Smith GP, Science 1985; 228:1315; Scott JK, Smith GP, Science 1990; 249:386; and Clackson T, Wells JA, Trends In these systems, peptides Biothechnol 1994; 12:173.) protein. fusion of a larger usually part Interaction between the peptide and its target molecule

[34]

may be weakened due to many degrees of conformational freedom as well as the peptide being "hidden" by the fusion protein. To overcome the above limitations, the ${\rm FliTrx}^{\rm TM}$ E. coli peptide display library (available from Invitrogen, Carlsbad, CA), a system incorporating the E. coli thioredoxin, is contemplated for the present invention. This system is shown in the illustration of Fig. 1.

As shown in Fig. 1, thioredoxin has a structurally rigid active site formed by the sequence - Cys32Gly33Pro34Cys35-. This sequence also forms a tight disulfide loop from the flanking cysteine residues and can accommodate a wide variety of short peptide insertions. The result is that the inserted peptide is presented in a constrained and exposed fashion that maximizes the binding to its target molecule.

Using this method, a 12 amino acid random library constructed within the thioredoxin peptide successfully utilized 100p was site active conjunction with a yeast "interaction-trap" to yield peptides with affinity to human Cdk2 according to Colas P. et al., in Nature 1996; 380:548. By inserting the entire thioredoxin gene into and replacing a central, nonessential portion of the E. coli flagellin gene, a chimeric protein ($\operatorname{FliTrx}^{\mathsf{TM}}$) was synthesized and exported to the cell surface of the E. coli. As a result, a peptide inserted within the active site of the ${\tt FliTrx}^{\tt TM}$ thioredoxin would reside on the external surface of the bacterium, maximizing its presentation to the external Using this methodology, a dodecapeptide environment. library within the ${
m FliTrx}^{
m M}$ thioredoxin active site was used successfully for selecting individual peptides with affinities for immobilized antibody targets.

One aspect of the present invention involves [35] the identification of novel markers on the endothelium specific for the tumor-endothelial cell association. The present invention preferably involves panning the ${
m FliTrx}^{
m M}$ peptide display library against a monolayer of Matrigel infiltrating cells (MAGIC) in order to remove potential clones binding to angiogenic markers. are angiogenic endothelial cells, which infiltrate a subcutaneous fibronectin growth factor and containing Matrigel® deposit (see Baatout S, Anticancer Res 1997; 17:451 and Ito Y et al., Int J Cancer 1996; 67:148, both of which are incorporated herein in their entirety by reference thereto). These cells lack tumor cell interaction and presumably should display only tumor-derived contrast, In markers. angiogenic endothelial cells (TDEC) are endothelial cells from a non-binding clones were subcutaneous tumor. The incubated with TDECs after "subtractive-panning" with The general panning protocol is shown and described in Fig. 2.

embodiment the present invention which is tumor-derived endothelial cells (TDEC) and Matrigel infiltrating cells (MAGIC), and the use of these techniques and cell populations together to substantially subtract out information not specifically related to endothelial cells.

[37] Clones binding to TDECs were then propagated, thus amplifying those clones displaying peptides with binding specificity to tumor endothelial cells. This

process was repeated five times, each time removing clones binding to MAGIC while enriching for those binding to TDEC. The results are shown in Fig. 2. Accordingly, an alternative embodiment of the present invention involves "subtractive panning," more specifically, "subtractive panning of TDEC minus MAGIC."

[38]

Specifically, one vial of FliTrx™ Peptide Library was used to inoculate 50 ml of IMC medium [1xM9 Salts (40mM Na₂HPO₄, 20mM KH₂PO₄, 8.5mM NaCl, 20mM NH₄Cl, pH 7.4), 0.2% casamino acids, 0.5% glucose, 1mM MgCl $_2$] containing 100 μ g/ml of ampicillin. The inoculated broths were grown overnight with shaking at 25°C until OD_{600} is approximately 3. From this culture, 10^{10} cells were added to 50 ml of IMC medium containing 100 $\mu g/ml$ each of ampicillin and tryptophan. This was to induce the expression of the peptides by the E. coli cells and was performed at 25°C with shaking for 6 hrs. After peptide induction, 1010 bacterial cells were layered on confluent MAGICs in a 60 mm dish. The incubation was performed at 4°C for 1 hr in the presence of 10% fetal calf serum (FCS) and 1% α -methyl mannoside. presence of FCS prevented nonspecific protein-protein binding, while that of α -methyl mannoside prevented nonspecific protein binding via lectin-like interactions. After 1 hour, the non-binding cells were transferred similar incubated under directly onto **TDECs** and conditions as that with MAGICs. The TDEC monolayer was washed 5 times with IMC medium containing 10% FCS and 1% $\alpha\text{-methyl}$ mannoside (wash solution) to remove non-binding Cells bound to TDECs were dislodged by vigorously vortexing the plate containing 0.75 ml of wash solution for 30 seconds. These cells were then amplified, re-induced for peptide expression, and the process of panning was repeated four additional times.

[39]

In order to survey for potential peptide sequences which will bind molecular markers specific for tumor-endothelial interaction, inserts encoding for the displayed peptides from 100 randomly picked bacterial clones were sequenced. This was accomplished Frozen stocks of cells from the fifth panning samples were plated at various dilutions on RMG-Amp agar plates (1xM9 salts, 0.2% casamino acids, 0.5% glucose, 1mM MgCl₂, 100μ g/ml ampicillin) at 30° C overnight. hundred individual colonies were picked the following day and were used to inoculate 3 ml of RM medium (1xM9 2% casamino acids, 1% glycerol, The inocula were containing 100 μ g/ml ampicillin. incubated with shaking at 30°C for 16-18 hours until OD_{600} is between 2 and 3. Frozen stocks in 15% glycerol were made from 850 μl suspensions of each clone. remainder of each culture was used for plasmid DNA purification.

[40]

TDECs are endothelial cells isolated from SCC VII murine squamous cell tumors in C3H/HeJ mice as shown Tumors were established by subcutaneous in Fig. 3A. injection of 5×10^6 SCC VII cells per C3H/HeJ mouse. After a tumor had achieved a diameter of 0.5 cm to 1.0 cm and before any evidence of central necrosis, it was with digested sterilely, minced, and removed cell single yield collagenases and RNAses to a The cells were then stained using antibody suspension. The stained cells were sorted using automated flow cytometry and the positive cells were cultured as TDECs in Po Media [DMEM supplemented with [42]

20% Sarcoma-180 conditioned media, 10% Fetal Calf Serum, 1% BME vitamin, 1% heparin, and 0.005% endothelial cell growth supplement (Collaborative Research)].

shown in Fig. 3B. Approximately 7-10 days after the Matrigel® injection, the plug was removed and cultured in vitro in Po Media for additional 7-10 days. Single cell suspension was prepared by digesting the Matrigel® plug in Dispase®. The cells were then cultured in Po Media.

of for specific binding Evidence oligopeptides to TDEC was accomplished as follows. The most frequently repetitive sequences obtained from the 100 clones were used for synthesis of oligopeptides fluorescein conjugating Genesis). Вy termini the carboxyl (FITC) to isothiocynate peptides, these molecules were tested for in vitro binding with TDECs and NIH3T3 cells (negative control cell line). These peptides contained flanking cysteines loop may be reformed, disulfide a that constraining and mimicking the binding condition of the Positive and negative selection process. initial control peptides were PepRGD (H2N-Cys-Glu-Leu-Arg-Gly- ${f Asp} ext{-Gly-Trp-Cys-CO}_2{f H})$ and ${f PepG}_7$ (${f H}_2{f N} ext{-Cys-Gly}_7 ext{-Cys-CO}_2{f H})$, respectively. The control peptide PepG7 is not expected to have any specific binding to membrane proteins, while PepRGD has been reported to bind angiogenic endothelial cells, and therefore, should bind both MAGICs and TDECs. In some experiments, poly-L-lysine was also used as a Monolayers of NIH3T3 and positive control peptide. TDECs on glass slide wells were incubated with peptides at 5 $\mu \mathrm{g/ml}$ (1 $\mu \mathrm{g}$ of peptide per 200 $\mu \mathrm{l}$ well) overnight

[44]

at 37°C in phosphate buffered saline (PBS) with 10°FCS . After washing the cells with PBS with 10°FCS for 3 times at $37^{\circ}\text{C}/15$ minutes, fluorescent microscopy of the cells was performed.

[43] Following panning of the FliTrx library against MAGIC and TDEC, one hundred colonies were picked randomly for sequencing of the inserts. The resulting sequencing data were then analyzed for repeats. Those repeated sequences (3-mer or greater) are listed in Figure 4. There were a total of 17 repeat sequences isolated—thirteen 3-mers and four 4-mers.

of the peptide important conclusion An revealed a distinct charge motif. analysis individual amino acids were scored as positively charged (+), negatively charged (-), neutral and hydrophilic $(\bigcirc$, or neutral and hydrophobic (O) at physiologic This analysis revealed that of all the conditions. repeats, seventeen 3-mer clones (34% of analyzed clones, and twenty-three 3- or 4-mer clones or 46% of analyzed clones) depicted the positive-positive-hydrophobic motif (++O) as shown in Table 2.

Combining the data from Fig. 4 and Table 2, [45] five peptide sequences were identified to be tested for These five peptide TDEC. specificity to binding sequences are shown in Table 3 with the targeting residues illustrated by three-letter designations. The test peptides are labeled SEQ ID NO 1-5. The control peptide PepG7 consists of seven glycine residues flanked This peptide should have no binding by cysteines. specificity to TDEC and serves as the negative control peptide. PepRGD has reported specificity for tumor endothelium and serves as the positive control peptide.

determine the endothelial order to [46] specificity of the SEQ ID NO 1-5 peptides, in vitro binding experiments with TDEC monolayers were performed. In these experiments, NIH3T3 was used as the negative results of this binding The control monolayer. experiment are depicted in Figures 5 and 6. As shown in both Figs. 5 and 6, labeled SEQ ID NO 3 containing the targeting residues Arg-Arg-Leu consistently showed the brightest staining and specificity for TDEC. SEQ ID NO 2 with the targeting residues Arg-Lys-Leu also showed preferential staining for TDEC, however, binding of FITC labeled SEQ ID NO 2 to TDEC did not yield as high a level as did binding of SEQ ID NO 3 to TDEC. The targeting motifs of SEQ ID NO 3 and SEQ ID NO 2 both conform to the positive-positive-hydrophobic (++O) motif.

Additionally, in vivo experiments with the [47] prototype peptide, SEQ ID NO 3, which stained the brightest in the in vitro experiments described above, assays different conducted using several In one in vivo assay, tumor-bearing described below. mice were injected five times intravenously (tail vein) The mice were with 1 ng/mouse at one hour intervals. sacrificed 15 minutes after the final injection, the heart, muscle) tumors and other normal tissues (lung, were taken for fresh frozen sectioning (i.e., embedded and for evaluation via in OCT medium and frozen) The assay showed microscopy. fluorescence preferential binding of SEQ ID NO 3 for the vessels in the tumors, with no binding to the vessels of normal This result has been observed in murine SCC tissues. (squamous cell) as well as in human xenograft PC-3 tumor models. These (prostate carcinoma) illustrate the wide cross-reactivity of these peptides, especially that of SEQ ID NO 3. Although these peptides were generated from TDEC originating from the murine SCC tumor, SEQ ID NO 3 also bound to the endothelium from a human xenograft model.

[48] The specificity of SEQ ID NO 3 for endothelial vessels is illustrated in Figure 7. In this experiment, PC-3 tumor-bearing mice were injected (as

described above) with positive control poly-L-lysine, negative control peptide G7 and peptide SEQ ID NO 3. Fig. 7A, 7B and 7C are micrographs illustrating crosssections of PC-3 tumor from tumor-bearing mice that were In each figure, the gray injected with peptides. diamond indicates the location of the lumen of the blood vessel. Fig. 7B is the negative control injection, G7, which showed no binding activity. Fig. 7C displays the distribution of SEQ ID NO 3 binding following injection. An intense binding to the cells of the vessel observed. staining was limited to the blood vessel wall, i.e. endothelial cells.

[49]

The ability of novel peptide motifs of the present invention to cross-react with tissues different sources was tested using human samples from a pathologist-diagnosed soft tissue sarcoma and a prostate carcinoma. Fresh frozen tumor sections were snap fixed and then triple stained paraformaldehyde, fluorescence microscopic analysis, the results of which are shown in Fig. 8. The staining included: a stain for cell nuclei, and anti-Factor VIII antibody (secondary antibody labeled with Cy3 red fluorescent probe), and peptide SEQ ID NO 3 (tagged with FITC, green upon Analysis revealed even, ubiquitous fluorescence). staining for cell nuclei indicating cell-dense tissue Factor VIII staining (marked with smaller sections. arrowheads) demonstrated that the tumor sections were vascularized and that there were vessel-like areas, some in cross-section, but many in longitudinal section. Factor VIII staining is specific for endothelial cells which produce and store the Factor VIII blood factor. Staining for SEQ ID NO 3 (marked with large arrowheads) was observed primarily in the regions of the tissue that were vascularized as indicated by staining with Factor VIII. These data show that ++O motif peptide sequences, with SEQ ID NO 3 as the model, are specific for the endothelium of tumors, and importantly that the motif specificity is not limited to a particular species.

[50]

These peptides are likely to have significant applications in human cancer therapeutics. molecules that are able to bind to tumor endothelium specifically could be used as a delivery vehicle for carrying cytotoxic agents to the tumor. Importantly, the novel peptides of the present invention are small, preferably less than 50 amino acid residues in length, and therefore are unlikely to elicit unwanted immune selective The in the host. responses concentration of the cytotoxic agent within the tumor would affect not only the endothelial cells but also the Mortality due to cancer is the result of tumor cells. uninhibited and metastatic growth of the cancer made possible by the tumor vasculature. Therefore, the ability to destroy tumor vasculature leading to deterred cancer growth and metastasis would impact significantly on the natural outcome of this disease process.

[51]

Aside from therapeutic targeting of the tumor vasculature, targeting peptides of the present invention that specifically bind to tumor endothelium can be used as a possible diagnostic tool. The small size of the peptides of the present invention are also desirable for these diagnostic purposes. For example, patients can present with occult tumors, or with nonspecific

It is most preferable to have a peptide sequence which includes a positive-positive-hydrophobic motif.

The agent that is linked to the targeting [53] of course, depend on the ultimate peptide will, application of the invention. Where the aim is to provide an image of the tumor, one will desire to use a diagnostic agent that is detectable upon imaging, such as a paramagnetic, radioactive or fluorogenic agent as described and disclosed in U.S. Patent 6,051,230 which is incorporated by reference herein in its entirety. Many diagnostic agents are known in the art to be useful methods for their imaging purposes, are as for attachment to antibodies (see, e.g., U.S. Pat. Nos. 5,021,236 and 4,472,509, both incorporated herein by reference). In the case of paramagnetic ions, one might mention by way of example ions such as chromium (III), manganese (II), iron (III), iron (II), cobalt (II), nickel (II), copper (II), neodymium (III), samarium (III), ytterbium (III), gadolinium (III), vanadium (II), terbium (III), dysprosium (III), holmium (III) and gadolinium being particularly (III), with erbium preferred. Ions useful in other contexts, such as X-ray imaging, include but are not limited to lanthanum (III), gold (III), lead (II), and especially bismuth (III). Moreover, in the case of radioactive isotopes for therapeutic and/or diagnostic application, one might mention iodine¹³¹, iodine¹²³, technicium⁹⁹, indium¹¹¹, rhenium¹⁸⁸, rhenium¹⁸⁶, gallium⁶⁷, copper⁶⁷, yttrium⁹⁰,

iodine 125 or astatine 211.

[54]

For certain applications, it is envisioned that the therapeutic agents will be pharmacologic agents will serve as useful agents for attachment to antibodies or growth factors, particularly cytotoxic or otherwise anticellular agents having the ability to kill suppress the growth or cell division of endothelial cells. In general, the invention contemplates the use of any pharmacologic agent that can be conjugated to a targeting peptide and delivered in active form to the tumor endothelium. Exemplary anticellular targeted agents include chemotherapeutic agents, radioisotopes as well as cytotoxins. In the case of chemotherapeutic agents, the inventors propose that agents such as a hormone such as a steroid; an antimetabolite such as cytosine arabinoside, fluorouracil, methotrexate aminopterin; an anthracycline; mitomycin C; a vinca alkaloid; demecolcine; etoposide; mithramycin; or antitumor alkylating agent such as chlorambucil be particularly preferred. melphalan, will embodiments may include agents such as a coagulant, a cytokine, growth factor, bacterial endotoxin or the lipid A moiety of bacterial endotoxin. In any event, it is proposed that agents such as these may, if desired, targeting successfully conjugated to a preferably an antibody, in a manner that will allow release internalization, targeting, their presentation to blood components at the site of the targeted endothelial cells as required using known conjugation technology (see, e.g., Ghose et al., 1983 and Ghose et al., 1987).

[55]

In certain preferred embodiments, therapeutic agents will include generally a plant-, fungus- or bacteria-derived toxin, such as an A chain toxins, a

[57]

ribosome inactivating protein, .alpha.-sarcin, aspergillin, restrictocin, a ribonuclease, diphtheria toxin or pseudomonas exotoxin, to mention just a few examples. The use of toxin-antibody constructs is well known in the art of immunotoxins, as is their attachment to antibodies. Of these, a particularly preferred toxin for attachment to antibodies will be a deglycosylated ricin A chain. Deglycosylated ricin A chain is preferred because of its extreme potency, longer half-life, and because it is economically feasible to manufacture it a clinical grade and scale.

Details on techniques for formulation and administration of pharmaceuticals may be found in the latest edition of Remington's Pharmaceutical Sciences (Mack Publishing Co., Easton, PA).

As recapitulated herein, embodiments of the invention correspond to specific novel peptide sequences which define specificity of tumor-derived endothelial cells (TDEC). The physical characteristic of charge conformation of these motifs is important, specifically, peptides containing the charge motif of positive-positive-hydrophobic. Identification of novel peptides and their corresponding charge motifs will be useful in diverse diagnostic tests and therapeutic treatments.

Although the preferred methods have been described in detail, it should be understood that various changes, substitutions, and alterations can be made in the present invention without deviating from the concepts provided herein. For example, the preferred peptide sequences can be included in synthetic proteins as well as a variety of therapeutic formulations.
